

Galadriel needs you!

Next week is Galadriel's birthday and she wants to celebrate a big party in Lothlórien. She wants to invite the members of the fellowship of the ring, but she can't remember their names and addresses, so it is impossible for her to send them an invitation.

She has got an **XML document** with this information, but she doesn't feel like reading it with all those annoying tags. She has tried to see the content in the browser, but, without any formatting, it is very confusing and she can't transform it, because she refused to learn XSL when the teacher explained it (you see? This is important!).

Would you help Galadriel with her problem? (I know you will)

She wants you to write a transformation, so the output is an **HTML document** that she can open in her browser. She wants a **table with three columns**: name, surname and address (where does the person live), and a row with this information for each member of the fellowship. Be careful and **don't include those ones that won't be able to come** to the party (maybe Boromir is busy, if you know what I mean...).

One last thing! Her assistants keep asking her about the number of attendees, in order to organise the event, but she doesn't know how to use XPath functions either, so she can't **count how many members of the fellowship will come**. Could you include the number too?

You already have the XML document and this is an example of how Galadriel wants the output to look like:

Members of the fellowship of the ring that will come to the party:

Name	Surname	Address
Gandalf		Aman
Aragorn		Gondor
Frodo	Baggins	The Shire
Samwise	Gamgee	The Shire
Peregrin	Took	The Shire
Meriadoc	Brandybuck	The Shire
Legolas		Mirkwood
Gimli		Ered Luin

Number of attendees: 8

Thank you for helping Galadriel!
